

Power at c.bm = 0.45: three DGP/analysis combinations

Same three designs, same carryover grid, N = 70 total per design. The $t_{1/2} = 0$ column is the zero-carryover baseline; comparing it against $t_{1/2} = 0.5$ and $t_{1/2} = 1$ within a panel shows carryover's impact for that DGP/analysis combination.

A and B: 1,000 reps/cell. Hendrickson–original: 300 reps/cell, its own published analysis model (random–intercept lmer, fixed non–half–life–tracking Dbc), not this paper's corCAR1 model.
